Abstract We survey the literatures on the economic consequences of the structure of social networks. We develop a taxonomy of "macro" and "micro" characteristics of social interaction networks and discuss both the theoretical and empirical findings concerning the role of those characteristics in determining learning, diffusion, decisions, and resulting behaviors. These complementarities can then feed back and affect the social network in which an individual resides, as they may constitute relevant components of the decision to invest in relationships. This, in turn, can reinforce behaviors and erode investments in more productive human capital and opportunities. Economic inequality generally refers to the disparity of wealth or income between different groups or within a society. Often characterized by the aphorism "the rich get richer while the poor get poorer," the phrase often refers more specifically to the gap in income or assets between the poorest and richest segments of an individual nation. Even though the basic concept has entered the public consciousness, the effects of highly concentrated wealth are hotly debated and poorly understood by observers. Although redistributive policies generally benefit all members of a society, the majority of the costs for those social benefits are borne by the wealthy segments of society. The Disadvantages of Economic Inequality. Inequality Stifles Growth. The consequences of stunting on education are also dramatic. Various studies show that child stunting is likely to impact brain development and impair motor skills. Malnutrition also slows economic growth and perpetuates poverty. Mortality and morbidity associated with malnutrition represent a direct loss in human capital and productivity for the economy. At a microeconomic level, it is calculated that 1 percent loss in adult height as a result of childhood stunting equals to a 1.4 percent loss in productivity of the individual.
