Therefore, we verified the phenomenon of adsorption to containers using various types of basic compounds and peptides (trypsin digested myoglobin and BSA) as models. The results showed that the adsorption phenomenon was different for each type of containers (glass versus PP vials) and confirmed that the vial adsorption phenomenon was one of factors that compromised the reliability of analytical results obtained. Adsorption is a unit operation in which dissolved constituents are removed from the solvent (water) by transfer to the surfaces of an adsorbent particle. Solid phase. Liquid phase. ADSORPTION contâ€™™d. Sorption is a general term which refers to the action of absorption or adsorption. Adsorption â€™“ chemicals adhere to surface of solid (dominant mechanism). Absorption â€™“ chemicals penetrate into solid, forming solid solution. Adsorbent â€™“ adsorbing phase Adsorbate â€™“ chemical being adsorbed. ADSORPTION contâ€™™d. 1. To demonstrate the adsorption phenomena. 2. To show students how to determine the adsorption parameters. TheoryÂ In adsorption process, two substances are involved. One is the solid or the liquid on which adsorption occurs and it is called adsorbent. The second is the adsorbate, which is the gas or liquid or the solute from a solution which gets adsorbed on the surface. Adsorbent: The substance on whose surface the adsorption occurs is known as adsorbent.
