A breast biopsy is the removal of a sample of breast tissue so that it can be tested for breast cancer. This can be done in a few ways. With a core needle biopsy, ultrasound or MRI guidance may be used. With an open procedure, stereotactic surgery or wire localization may be recommended to make sure the biopsy samples the abnormality. Even if you receive a preliminary report at the time of the biopsy, the final pathology report and further tests, if needed, often take at least a few days to complete. Biopsy results are negative, positive, or inconclusive; in the case of the latter, another biopsy or other studies may be needed. Findings may be listed on the report as The core biopsy—a minimally invasive procedure—is a common first-line approach to diagnose a breast mass, calcifications or enhancement (MRI). Occasional patients present with a palpable mass that is easily accessed with a Tru-cut type core biopsy apparatus. More commonly, core biopsies are performed to diagnose abnormalities found in the course of screening mammography & require image-guidance of some type because they are well below skin level & are otherwise not evident.
